INTRODUCTION

The code implements a client and project management system designed to handle clients, projects, and their associated invoices. It consists of three main classes: `Client`, `Project`, and `Invoice`.

1. Client: Stores client information, including an ID, name, and lists of their projects and invoices.
2. Project: Tracks projects associated with a client, including the project ID, name, total budget, and the amount already invoiced.
3. Invoice: Represents an invoice issued for a project, with attributes like invoice ID, amount, and status (Paid/Unpaid).

Key functionalities include adding new clients and projects, generating invoices with validations to ensure the invoice does not exceed the project's budget, and calculating due and paid amounts for each project. A simple interactive menu allows the user to manage clients, projects, and invoices dynamically.

OBJECTIVE

The objective of the code is to create a basic system for managing clients, their projects, and associated invoices. It aims to streamline the tracking of project budgets, invoice generation, and payment statuses, ensuring that invoices do not exceed project limits. Additionally, the system provides an interactive interface for adding and managing clients, projects, and invoices, while calculating and displaying due and paid amounts for each project, facilitating efficient financial management.

METHODOLOGY

1. Class Definitions: The code defines three primary classes—`Client`, `Project`, and `Invoice`—to encapsulate client data, project details, and invoice information.

2. Data Management: Clients are stored in a dictionary, where each client can have multiple projects and invoices linked to them. Projects are associated with a client by their unique IDs.

3. Invoice Validation: Invoices are generated only if the requested amount does not exceed the remaining budget for a project. The system automatically updates the invoiced amount for the project.

4. Interactive Functions:

- Functions for adding clients, projects, and invoices are interactive and prompt the user for input.
- The `calculate_project_amounts` function tracks due and paid amounts for each project by checking the status of associated invoices.

5. User Interface: A command-line interface allows users to add and manage clients, projects, and invoices and view client information, with simple options for navigating the system.

This approach ensures the accurate tracking of client projects and their financial progress while preventing over-invoicing.

RESULTS/FINDINGS

1. Client and Project Tracking: The system successfully tracks multiple clients, their associated projects, and invoices. Each client can have multiple projects, and each project can have multiple invoices.

2. Invoice Generation Control: The code ensures that invoices are generated only within the available project budget. This prevents over-invoicing, maintaining accuracy in financial tracking.

3. Financial Overview: The code effectively calculates and displays the due and paid amounts for each project, giving a clear picture of the project's financial status.

4. Error Handling: The system handles common errors, such as invalid client or project IDs and attempting to invoice beyond the project budget, by providing clear feedback to the user.

5.User Interaction: The interactive command-line interface allows users to easily add clients, projects, and invoices, making the system simple to use for managing client financial data.

CONCLUSION

The code provides a functional and straightforward system for managing clients, projects, and invoices. By organizing data into well-structured classes and ensuring proper validation of financial transactions, the system effectively tracks project budgets and ensures that invoicing stays within limits. The interactive interface simplifies user engagement, enabling easy management of clients and their associated projects. Overall, the system enhances financial oversight and ensures error prevention, making it a practical tool for basic client and project management needs.
